

# The Seven Sisters: Prime Generation based on the Form $2p + k$

ALLEN PROXMIRE\*

## Abstract

This computational note explores the frequency with which simple linear offsets, in the form  $2p + k$ , generate additional primes from a given prime  $p$ . The analysis, conducted on the first one million primes, utilizes seven specific offsets:  $k \in \{+1, +3, -3, -5, +7, +9, -9\}$ . We find that this set of "Seven Sisters" produces additional primes at a remarkable **80.15%** success rate, with at least one offset yielding a prime in **64.71%** of cases.

Another key finding is the significant increase in success rates for offsets  $k = +1, +7$ , and  $-5$  when candidates are filtered for divisibility by 3 and 5. This effect is a direct consequence of predictable modular relationships between the primes and these specific offsets. After this filtering, all successful offsets converge to a similar success rate of approximately 22%, with the notable exception of the  $2p + 7$  offset, which consistently achieves a higher success rate of around 26.25%. This offset's unique behavior, along with the unique ability of  $2p - 5$  to produce a prime in all ending-digit categories, represents a compelling pattern in prime number distribution and an efficient methodology for primality production.

Full data, code, and analysis are available at:

## 1. Introduction

The study of prime numbers has fascinated mathematicians for centuries, with many questions still unanswered. One area of interest is the relationship between prime numbers and formulas that generate new primes, as potential glimpses into the underlying structure of prime distribution. This paper investigates the formula  $2p + k$ , a simple linear transformation of a prime number, with seven specific offsets, to see how frequently it results in another prime. We hypothesize that the success rates for these seven offsets are not random and are influenced by the modular properties of both the primes and the offsets themselves. By analyzing the data and filtering for common composite factors, we aim to uncover underlying patterns that dictate the success or failure of this formula.

We call the offsets:  $2p + 1$ ,  $2p + 3$ ,  $2p - 3$ ,  $2p - 5$ ,  $2p + 7$ ,  $2p + 9$ , and  $2p - 9$ , the Seven Sisters. One of whom is Sophie Germain, who notably studied the form  $2p + 1$ .

## 2. Methodology

Python scripts were developed to conduct this analysis. The scripts first generated a large list of primes using the Sieve of Eratosthenes to serve as an efficient lookup table. We then iterated through the first one million primes, skipping 2 and 5 as they do not end in 1, 3, 7, or 9. For each prime, the seven offsets were applied.

The resulting candidate numbers were then checked for primality using the pre-generated lookup table. The results were categorized by the ending digit of  $p$ , the original, input-prime (either 1, 3, 7, or 9). In a subsequent step, a filter was applied to remove any candidates that were multiples of 3 or 5, and the analysis was re-run to determine the new success rates.

## 3. Results and Key Findings

Python code and data are available at the GitHub link provided.

The initial analysis showed that the Seven Sisters are highly effective, collectively producing at least one prime 65% of the time, and producing a unique prime 80% of the time. The distribution of success counts are detailed in Table 1.

**Table 1. Exact and Cumulative Results**

|                                       |         |            |

| at least 2 | 239268 | 23.93% |
| at least 1 | 647054 | 64.71% |

The initial analysis also examined the success rates of each individual offset, which are summarized in Table 2. Results were varied with four offsets showing a success rate of 16.4% and the others between 8-11%.

**Table 2. Individual Offset Success**

|                                  |           |            |
|----------------------------------|-----------|------------|
| Individual offset success counts |           |            |
| Total primes considered          | 1000000   |            |
| Offset                           | Successes | Percentage |
| $2p - 9$                         | 164067    | 16.41%     |
| $2p - 5$                         | 109637    | 10.96%     |
| $2p - 3$                         | 163897    | 16.39%     |
| $2p + 1$                         | 82237     | 8.22%      |
| $2p + 3$                         | 164061    | 16.41%     |
| $2p + 7$                         | 98463     | 9.85%      |
| $2p + 9$                         | 164181    | 16.42%     |

Additionally, the success rates of each individual offset were categorized by the ending-digit of  $p$ , the initial input-prime (either 1, 3, 7, or 9) as shown in Table 3. As expected, the success of the offsets are dependent upon the ending-digit of  $p$ . Also, as expected, the offsets work better for some ending-digits than others, but averaged together equal the totals in Table 2.

A significant observation is that the  $2p - 5$  offset is the only offset to succeed in all prime ending-digit categories.

**Table 3. Individual offset success by ending-digit of  $p$**

| Prime Ending | Offset   | Total Primes | Successful Primes | Other Composites | Success Rate (%) |
|--------------|----------|--------------|-------------------|------------------|------------------|
| ending_1     | $2p - 9$ | 249934       | 54815             | 195119           | 21.9318          |

|              |        |              |                   |                  |                  |
| Prime Ending | Offset | Total Primes | Successful Primes | Other Composites | Success Rate (%) |
| ending_9     | 2p -9  | 249940       | 54572             | 195368           | 21.834           |
| ending_9     | 2p -5  | 249940       | 27662             | 222278           | 11.0675          |
| ending_9     | 2p -3  | 249940       | 0                 | 249940           | 0                |
| ending_9     | 2p + 1 | 249940       | 27273             | 222667           | 10.9118          |
| ending_9     | 2p + 3 | 249940       | 54760             | 195180           | 21.9093          |
| ending_9     | 2p + 7 | 249940       | 0                 | 249940           | 0                |
| ending_9     | 2p + 9 | 249940       | 54535             | 195405           | 21.8192          |

Subsequently filtering the results in Table 3 for multiples of 3 and 5, results in the following observations, and are shown in Table 4. The seven offsets can be divided into two groups based on the effect of the filter:

- Group 1: No Effect on Success Rate: For the offsets  $2p + 9$ ,  $2p - 9$ ,  $2p + 3$ , and  $2p - 3$ , the success rate remained unchanged after filtering. This indicates that candidates from these offsets were rarely, if ever, multiples of 3 or 5, making the filter negligible.
- Group 2: Doubling of Success Rate: For the offsets  $2p + 1$ ,  $2p + 7$ , and  $2p - 5$ , the success rates jumped dramatically, almost doubling in each case in which the offset worked. For instance, the initial success rate for the  $2p - 5$  offset with primes ending in 1 was approximately 10.92%. After filtering out candidates that were multiples of 3 or 5, the success rate for this same offset and prime group jumped to approximately 21.82%.

Again, the  $2p - 5$  offset is the only one to succeed in all prime ending categories. After filtering, all offsets that yield any successful primes achieve a similar success rate of approximately 22%, with the notable exception of  $2p + 7$ . This offset consistently achieved a higher success rate of approximately 26.25% in all ending-digit categories except when ending in 9, for which  $2p + 7$  is not prime.

**Table 4. Results filtered for multiples of 3 and 5**

| Prime Ending | Offset   | Total Primes | Successful Primes | Not a Multiple of 3 and/or 5 | Success Rate (%) |
|--------------|----------|--------------|-------------------|------------------------------|------------------|
| ending_1     | $2p - 9$ | 249934       | 54815             | 249934                       | 21.9318          |

## 4. Discussion: The Role of Modular Arithmetic

The distinct behaviors observed in our two groups of offsets are not coincidental; they are a direct consequence of modular arithmetic, specifically how the offsets interact with the properties of the primes themselves. We can explain these behaviors by examining the value of  $2p + k$  modulo 3.

### Group 1: Unaffected Offsets

For the offsets  $k \in \{+3, -3, +9, -9\}$ , the resulting candidate number  $2p + k$  is never a multiple of 3. We can prove this by examining the congruence classes of primes. Every prime  $p > 3$  is either congruent to 1 or 2 modulo 3.

- If  $p \equiv 1 \pmod{3}$ : The candidate is  $2p + k \equiv 2(1) + k \pmod{3}$ . For  $k \in \{+3, -3, +9, -9\}$ , we have  $k \equiv 0 \pmod{3}$ . Therefore,  $2(1) + k \equiv 2(1) + 0 \equiv 2 \pmod{3}$ .
- If  $p \equiv 2 \pmod{3}$ : The candidate is  $2p + k \equiv 2(2) + k \pmod{3}$ . For  $k \in \{+3, -3, +9, -9\}$ , we have  $k \equiv 0 \pmod{3}$ . Therefore,  $2(2) + k \equiv 4 + 0 \equiv 1 \pmod{3}$ .

In both cases, the resulting candidate is never divisible by 3. This explains why filtering out multiples of 3 had no effect on the success rates for this group of offsets.

## Group 2: Filter-Affected Offsets

For the offsets  $k \in \{+1, +7, -5\}$ , the resulting candidate number  $2p + k$  is guaranteed to be a multiple of 3 for one of the two prime congruence classes (either  $p \equiv 1 \pmod{3}$  or  $p \equiv 2 \pmod{3}$ ).

- Offset  $2p + 1$ :
  - If  $p \equiv 1 \pmod{3}$ , then  $2p + 1 \equiv 2(1) + 1 \equiv 3 \equiv 0 \pmod{3}$ .
  - If  $p \equiv 2 \pmod{3}$ , then  $2p + 1 \equiv 2(2) + 1 \equiv 5 \equiv 2 \pmod{3}$ .
- Offset  $2p - 5$ :
  - If  $p \equiv 1 \pmod{3}$ , then  $2p - 5 \equiv 2(1) - 5 \equiv -3 \equiv 0 \pmod{3}$ .
  - If  $p \equiv 2 \pmod{3}$ , then  $2p - 5 \equiv 2(2) - 5 \equiv -1 \equiv 2 \pmod{3}$ .
- Offset  $2p + 7$ :
  - If  $p \equiv 1 \pmod{3}$ , then  $2p + 7 \equiv 2(1) + 7 \equiv 9 \equiv 0 \pmod{3}$ .
  - If  $p \equiv 2 \pmod{3}$ , then  $2p + 7 \equiv 2(2) + 7 \equiv 11 \equiv 2 \pmod{3}$ .

Since the population of primes is split almost equally between the two congruence classes, approximately half of all candidates generated by these offsets are guaranteed to be multiples of 3. Our filter effectively removes this large pool of guaranteed composites, revealing the primes generated by the other half, which is why the success rate for this group appears to double.

## Unique Behaviors

The data reveals two especially compelling patterns:

- Offset  $2p - 5$ : This offset is the only one to produce primes across all four ending-digit categories of the input prime. While it is obvious that  $2p - 5$  cannot equal a multiple of 5, it is not obvious how it avoids other prime factors. This suggests a unique and stable relationship that warrants further investigation.
- Offset  $2p + 7$ : After filtering, this offset consistently outperformed all others, achieving a success rate of 26.25% in three of the four categories. This superior performance is a

crucial finding that challenges the notion of a uniform prime distribution even after modular filtering and deserves dedicated future study.

This illustrates how a simple filter based on a number's prime factors can reveal deeper, non-obvious patterns in the distribution of primes.

## 5. Conclusion

This study demonstrates that the **Seven Sisters** — a simple linear formula of the form  $2p + k$  applied to a given prime — can serve as an efficient engine for prime number generation. The high success rates observed, with a unique prime generated in over 80% of cases and at least one prime in over 64% of cases, underscore the remarkable generative power of this method. The application of a filter for the multiples of 3 and 5 creates a more accurate picture of each offset's true effectiveness by removing predictably composite candidates.

Specifically, the unique behaviors of the  $2p - 5$  and  $2p + 7$  offsets highlight that prime distribution is not uniform even within the confines of this formula. The ability of  $2p - 5$  to produce a prime in every prime ending-digit category and the consistently superior performance of  $2p + 7$  after filtering warrant further research.

This methodology presents a practical and effective approach to primality production and offers a rich area for continued computational and theoretical exploration into the patterns underlying prime number sequences.
